Intractability assumptions on module lattices an overview

Damien Stehlé

ENS de Lyon

PQCRYPTO, July 2021

Why module lattices?

By relying on lattice problems restricted to **module lattices**, one gets cryptographic constructions that are **efficient** and presumably **quantum-safe**.

[NIST finalists]	

Module lattices have been around in cryptography for 25 years [HPS98]

Goal of this talk

A high-level overview of the module hardness assumptions and their relationships

Note: not sufficient for concrete security analysis of concrete schemes

- other assumptions (e.g., ROM, decryption errors),
- strectched assumptions (e.g., very small secrets, sparse secrets),
- concrete security versus asymptotic hardness,
- side-channel attacks.

Reductions considered in this talk may lose some small factors in problem parameters and may possibly be

sub-exponential, quantum and non-uniform.

Algorithms may be as such, and also heuristic.

Roadmap

- Module lattices
- Ring-LWE
- Module-LWE
- NTRU

Polynomial rings

Let $\Phi \in \mathbb{Z}[x]$ be monic and irreducible.

E.g.:
$$\Phi = x^d + 1$$
 for d a power of 2.

We define

$$R = \mathbb{Z}[x]/\Phi$$
 and $K = \mathbb{Q}[x]/\Phi$.

K is the number field corresponding to Φ .

R may not correspond to its ring of integers. But:

- heuristically, it does in $\approx 60\%$ of cases,
- for most of the talk, the discrepancy does not matter,
- for simplicity, we assume they are the same.

Integral R-modules

The *R*-modules of this talk

An (integral) R-module is a subset M of an R^k (for some $k \ge 1$) that is stable under multiplication by R:

$$\forall r \in R, \forall \mathbf{b} \in M : r \cdot \mathbf{b} \in M$$

For
$$d=1$$
: we recover (integral) lattices

For
$$k = 1$$
:
we recover ideals of R , i.e., $I = r_1 \cdot R + \ldots + r_t \cdot R$.
(we can always choose $t = 2$)

Pseudo-bases

Every module $M \subseteq R^k$ is of the form $M = \sum_{i < k} I_i \cdot \mathbf{b}_i$

Module lattices

Let's identify $\mathbb{Z}[x]/\Phi$ with \mathbb{Z}^d via polynomial coefficients.

$$P \in R$$
 is identified to $(P_i)_{i < d} \in \mathbb{Z}^d$
 R is identified to \mathbb{Z}^d
 R^k is identified to $\mathbb{Z}^{d \cdot k}$
 $M \subseteq R^k$ module is identified to $L \subseteq \mathbb{Z}^{d \cdot k}$ lattice

The module geometry is inherited from the Euclidean norm in $\mathbb{R}^{d \cdot k}$.

Module lattice problems

Just lattice problems, restricted to module lattices. For k = 1, we call them ideal lattice problems.

 $\begin{array}{ll} \gamma\text{-SVP:} & \text{given a basis of a lattice,} \\ \gamma\text{-modSVP:} & \text{given a basis of a module lattice,} \\ \gamma\text{-idSVP:} & \text{given a basis of an ideal lattice,} \end{array} \quad \begin{array}{ll} \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_1 \\ \text{find } \mathbf{b} \text{ s.t. } 0 < \|\mathbf{b}\| \leq \gamma \cdot \lambda_$

Algorithms for module SVP

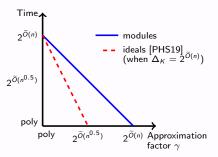

For $k \geq 2$:

[FS10]: recovers a short module pseudo-basis from a short lattice basis

[LPSW19]: generalizes LLL to module lattices

[MS20]: gives a BKZ-type algorithm for module lattices

but overall, nothing known that is better than for arbitrary lattices

Algorithms for γ -SVP in dimension $n = d \cdot k$

For
$$k = 1$$
 (ideals):

The multiplicative structure of the set of ideals can be exploited [CDW17,PHS19].

[PHS19] is heuristic, quantum, sub-exponential and non-uniform.

For the talk, by default: $\gamma = n^{O(1)}$ and $k \leq O(1)$

Roadmap

- Module lattices
- Ring-LWE
- Module-LWE
- NTRU

Ring-LWE [SSTX09,LPR10]

Search Ring-LWE with parameters $q \ge 2$ and $\alpha > 0$

Given $(a_1, a_1 \cdot s + e_1), \ldots, (a_m, a_m \cdot s + e_m)$, find s.

- m is arbitrary
- s is uniform in $R_q := R/qR$
- the a_i 's are uniform in R_q
- the coefficients of the e_i 's are Gaussian of standard deviation $\alpha \cdot q$

For m > 1, this is a Bounded Distance Decoding instance for the module:

$$M = \{ \mathbf{b} \in R^m, \exists s \in R : \mathbf{b} = \mathbf{a} \cdot s \bmod q \} = \mathbf{a} \cdot R_q + (q \cdot R)^m,$$

where the *i*-th entry of $\mathbf{a} \in R_q^m$ is a_i .

For the talk, by default: $q = d^{O(1)}$ and $1/\alpha = d^{O(1)}$

Polynomial rings or algebraic number theory

The Ring-LWE definition from [LPR10] differs in several respects, including

- the use of the ring of integers rather than $R = \mathbb{Z}[x]/\Phi$
- the use of duality
- an error covariance inherited from the canonical embedding geometry

Technically more convenient, but with some computational drawbacks:

- To build Ring-LWE samples, the ring of integers O_K must be known. In the worst-case, this requires a **factoring oracle**.
- To recognize short elements, one needs a short lattice basis of O_K .

 In the worst-case, this requires an **SIVP oracle**.

[RSW18]: These definitions are computationally equivalent

Decision Ring-LWE

Decision Ring-LWE with parameters $q \ge 2$ and $\alpha > 0$

Distinguish $\{(a_i, a_i \cdot s + e_i)\}_{i \leq m}$ from $\{(a_i, b_i)\}_{i \leq m}$

- the b_i 's are uniform in R_q
- all the rest is as in search Ring-LWE

Search Ring-LWE vs decision Ring-LWE

Search Ring-LWE reduces to decision Ring-LWE.

- For cyclotomics [LPR10]
- For all Φ's: [RSW18], based on the OHCP technique from [PRS17]

On the secret and noise

Ring-LWE with s uniform is computationally equivalent to Ring-LWE with s sampled from the error distribution [ACPS09].

Concerning the noise distribution:

- Search Ring-LWE reduces to itself with a different error distribution (including deterministic errors), for a relatively wide variety of error "distributions" [BLL+15,BGM+16,DSSS21]
- Only partial results for the decision variant [LW20]

Ring-SIS [PR06,LM06]

Ring-SIS with parameters $q \ge 2$ and $\beta > 0$

Given (a_1,\ldots,a_m) uniform in R_q find $\mathbf{e}\in R^m$ such that

- $e_1 a_1 + \ldots + e_m a_m = 0 \mod q$,
- $0 < \|\mathbf{e}\| \le \beta$.

For m > 1, this is a Shortest Vector Problem instance for the module:

$$M = \{ \mathbf{e} \in R^m, e_1 a_1 + \ldots + e_m a_m = 0 \mod q \}$$

Ring-SIS and Ring-LWE are computationally equivalent ([SSTX09], based on the quantum reduction of [Regev05])

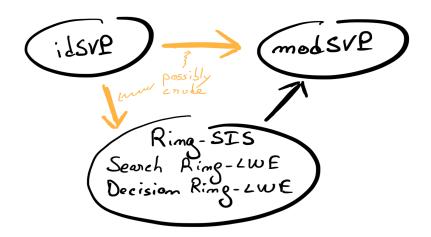

Worst-case hardness

(Worst-case) idSVP reduces to (average-case) Ring-SIS/Ring-LWE.

What to make of this result?

- it does not help setting Ring-LWE parameters,
 but gives an argument that Ring-LWE captures all the hardness of idSVP
- idSVP seems easier to solve (this was not known at the time)

Reductions so far

Module-LWE [BGV12,LS15]

Module LWE with parameters $q \ge 2, \alpha > 0$ and $k \ge 1$

Given $(a_1, \langle a_1, s \rangle + e_1), \dots, (a_m, \langle a_m, s \rangle + e_m)$, find s.

- m is arbitrary
- **s** is uniform in R_q^k
- the \mathbf{a}_i 's are uniform in R_q^k
- ullet the coefficients of the e_i 's are Gaussian of standard deviation $lpha \cdot q$

If m > k, this is a Bounded Distance Decoding problem instance for:

$$M = \left\{ \mathbf{b} \in R^m, \exists \mathbf{s} \in R^k : \mathbf{b} = \mathbf{A} \cdot \mathbf{s} \bmod q \right\} = \mathbf{A} \cdot R_q^k + (q \cdot R)^m,$$

where the *i*-th row of $\mathbf{A} \in R_q^{m \times k}$ is \mathbf{a}_i .

For the talk, by default: $q = d^{O(1)}$, $1/\alpha = d^{O(1)}$ and $k \leq O(1)$

Hardness of Module-LWE and variants

All the results mentioned earlier on Ring-LWE and Ring-SIS extend to module-LWE and Module-SIS.

Worst-case to average-case redution [LS15]

SIVP for rank-k modules reduces to Module-LWE in dimension k.

(SIVP: given a basis of a lattice L of dimension n, find $\mathbf{b}_1, \dots, \mathbf{b}_n \in L$ linearly independent and short compared to the n-th minimum of L)

Module-LWE and Ring-LWE

The q-ary decomposition trick [BLP+13,AD17].

$$\begin{split} \big(\sum_{i < k} a_i q^i\big) \cdot \big(\sum_{i < k} s_i q^i\big) & \approx \quad \big(a_0 \cdot s_{k-1} + \ldots + a_{k-1} \cdot s_0\big) \cdot q^{k-1} \mod q^k \\ & \approx \quad \big(\langle \mathbf{a}, \mathsf{rev}(\mathbf{s}) \rangle \mod q\big) \cdot q^{k-1} \end{split}$$

The \approx works only if the s_i 's are small.

$$\mathsf{Module} ext{-}\mathsf{LWE}_{k,q,lpha}\ pprox^c\ \mathsf{Ring} ext{-}\mathsf{LWE}_{q^k,lpha}$$

Module-LWE and Ring-LWE

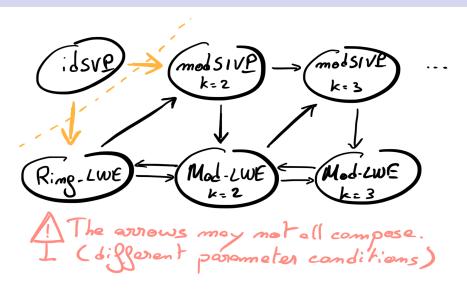

The q-ary decomposition trick [BLP+13,AD17].

$$\begin{split} \big(\sum_{i < k} a_i q^i\big) \cdot \big(\sum_{i < k} s_i q^i\big) & \approx \quad \big(a_0 \cdot s_{k-1} + \ldots + a_{k-1} \cdot s_0\big) \cdot q^{k-1} \mod q^k \\ & \approx \quad \big(\langle \mathbf{a}, \mathsf{rev}(\mathbf{s}) \rangle \mod q\big) \cdot q^{k-1} \end{split}$$

The \approx works only if the s_i 's are small.

Module-LWE_{k,q,\alpha}
$$\approx^c$$
 Ring-LWE_{qk,\alpha}

Reductions so far

Search NTRU [HPS98]

(Vectorial) search-NTRU with parameters $q \ge 2$ and $\beta > 0$

Given $h = f/g \mod q$, find the vector (f,g) (or a short multiple of it)

- f, g are random in R with g invertible modulo q,
- $||f||, ||g|| \le \beta$.

This is an SVP instance for the rank-2 module:

$$M = \left\{ (f, g) \in R^2 : g \cdot h = f \mod q \right\}.$$

When $\beta \ll \sqrt{q}$, this is a module variant of uniqueSVP:

$$\lambda_1(M) \approx \ldots \approx \lambda_d(M) \ll \lambda_{d+1}(M) \approx \ldots \approx \lambda_{2d}(M)$$

Decision NTRU

Decision-NTRU with parameters $q \ge 2$ and $\beta > 0$

Distinguish between $h = f/g \mod q$ and u, where

- f, g are random in R with g invertible modulo q,
- $||f||, ||g|| \le \beta$,
- u is uniform in R_q .
- When f and g are Gaussian with standard deviation $\gg \sqrt{q}$, Decision-NTRU is vacuously hard [SS11].
- For small f and g, Decision-NTRU reduces to Search-NTRU.

Little is known on the NTRU problem

Decision-NTRU is no harder than Ring-LWE

Dec-NTRU to modSIVP

If $h=f/g \mod q$ with f,g small, then $\lambda_{2d}(M) \approx \frac{q}{\beta}$ is large

Dec-NTRU to Ring-LWE [Peikert16]

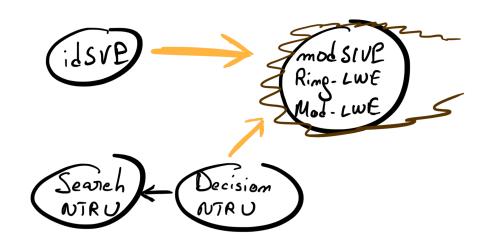

if h is uniform, $(s,e)\mapsto (h,hs+e)$ is injective else hs+e=h(s+g)+(e-1)

Interestingly, NTRU becomes weak when q is large and f, g are small.

- First proved when the field K admits appropriate subfields [ABD16,CJL16]
- In fact, lattice reduction suffices [KF17]

Given these attacks, the NTRU to Ring-LWE reductions above are very crude.

Where is NTRU?

idSVP reduces to NTRU [PS21]

Take $I = z \cdot R$ a principal ideal.

The following is a reduction from idSVP to Search-NTRU:

$$z \mapsto \lfloor q/z \rfloor \mod q$$

Let $g = z \cdot r$ be a short element of I. Then:

$$g \cdot \lfloor q/z \rceil = g \cdot (q/z + \{q/z\}) = q \cdot r + g \cdot \{q/z\}.$$

Hence

$$|q/z| = (g \cdot \{q/z\})/g \mod q.$$

- Generalizes to non-principal ideals
- Can be combined with the wc-to-ac idSVP self-reduction from [BDPW20]
- Leads to a sub-exponential time reduction from worst-case idSVP for $\gamma=d^{O(1)}$ to some average-case NTRU with $q=d^{\widetilde{O}(1)}$

Search versus decision

Given one NTRU sample, we can get many

$$h = f/g \mapsto x_1 h + x_2 = (x_1 f + x_2 g)/g$$

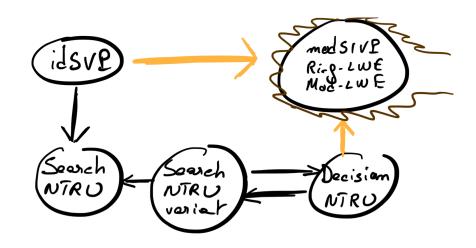

Now, by toggling the distributions of x_1 and x_2 and calling a decision-NTRU oracle, we can learn things about (f,g).

Given access to a decision NTRU oracle and an $h=f/g\in R_q$, one can recover $(f,g)\cdot R$

([PS21], using the OHCP technique from [PRS17])

- The reduction handles a lot of Search NTRU distributions for (f,g)
- This is not solving the vectorial Search NTRU problem
- [ABD16,CJL16,KF17] first find $(f,g) \cdot R$ and then (f,g).

NTRU, with the two new reductions

Importance of the choice of Φ

The choice of the defining polynomial Φ does not seem to matter much, at the high level we considered for the problems we considered

- For **principal ideals with a short generator** (sPIP), some Φ's make idSVP much easier [CDPR16,BBdV+17]
- The best known idSVP algorithms are faster for cyclotomics if we discard non-uniform algorithms [CDW17]

Can we show that all Φ 's are equally good? Is there a hard-core Φ ? Potential approach via Middle-Product LWE [RSSS17]

Better understand the relations between module problems

- Robustness of Decision Ring-LWE with respect to the "noise distribution"
- Can we reduce small rank modSIVP to rank-2 modSIVP? (like for modSVP [LPSW19,MS20])

NTRU seems to lie between idSVP and modSIVP for k > 2

- Is NTRU closer to idSVP or modSIVP?
- Is it an average-case variant of mod-uSVP in rank 2?
- Where does mod-uSVP lie between idSVP and modSVP or modSIVP?
- Is idSVP good enough for cryptographic constructions?

THANKS! 감사합니다!
